Conformational Variability – Experience with Ribosomes

Exploration of reconstruction strategy "High-resolution project"

Use small dataset (50,000) to optimize processing, with the idea to switch to larger dataset (130,000)

Parameters of image processing:

- Sampling (switch from coarse to fine)
- Window size (to avoid CTF effects)
- Angular spacing
- Amplitude correction in each step of refinement vs. at the very end

Final parameters:
angular step 0.5 degrees,
angular search range 2 degrees
7 iterations of refinement: 920 hours on a 48-node cluster
Regular window size OK
Sampling (decimation) can be switched mid-way from coarse to fine

Resolution measurement issues

- Apply soft mask to reconstruction to get true resolution!
- Evidence for dependence of resolution *R vs. log(N)*
- Is lin-log dependence general?
- Is it allowed to extrapolate from half to full dataset?

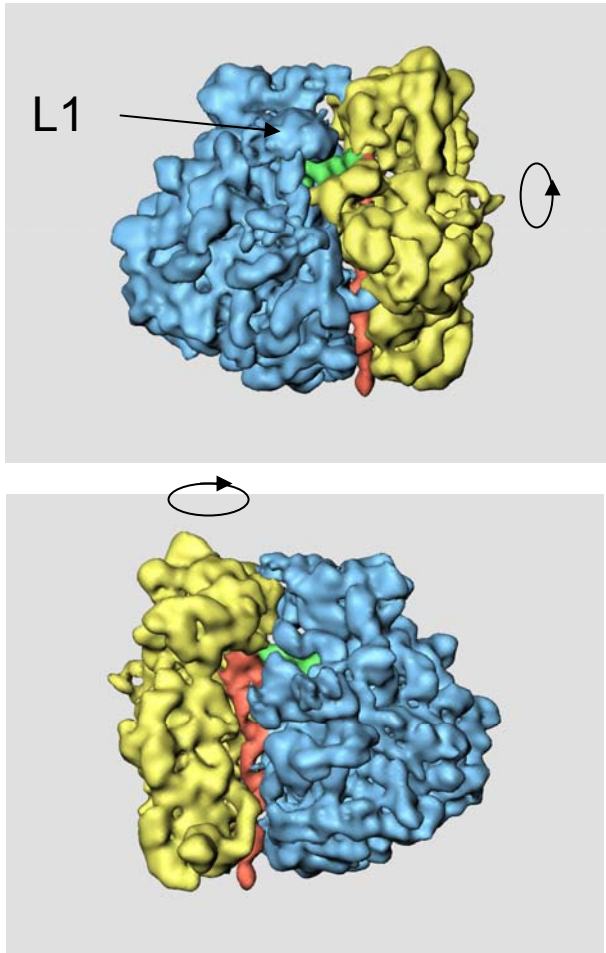
Dynamics of Translation

- We draw inferences about movements by comparing EM maps in different states.
- To what extent are such inferences supported by other data?

- L1 stalk move → X-ray
- Small subunit head rotation → X-ray
- Ratchet motion in translocation → smFRET
- tRNA selection → smFRET



Ratchet motion induced by EF-G binding

- Cryo-EM: (1) differences between conformations in two different states

  (2) evidence of conformational variability -- coexistence of different conformations in the specimen (blurring, 3D variance)
- Hydroxyl radical probing: changes of Pb^{2+} – induced rRNA cleavage pattern along elongation cycle (Polacek et al., 2000)
- Bulk FRET (Ermolenko et al., 2006)
- Single-molecule FRET (Cornish et al., 2007)

EF-G/eEF2 binding induces ratcheting of the small subunit

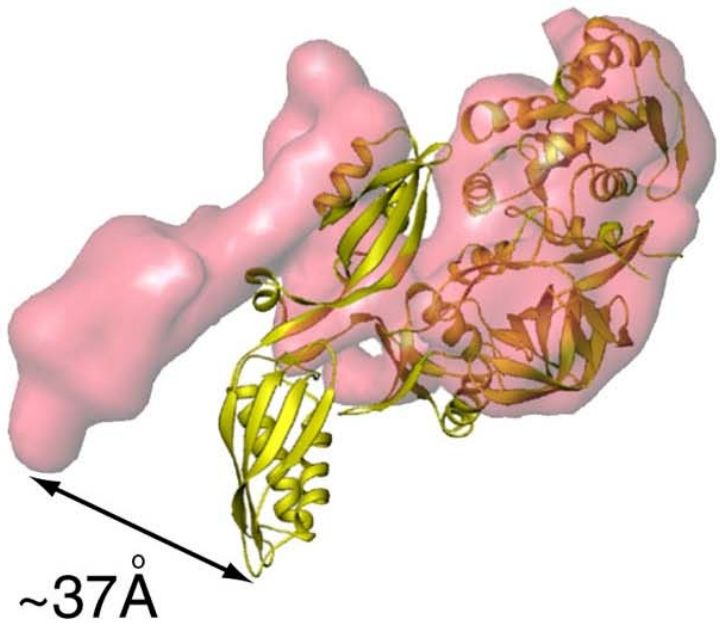
X-ray structure of EF-G•GDP, domains III, IV, V rotated

"Induced fit" – both ribosome and EF-G undergo structural changes, such that a match of binding sites is achieved



X-ray structure of EF-G•GDP

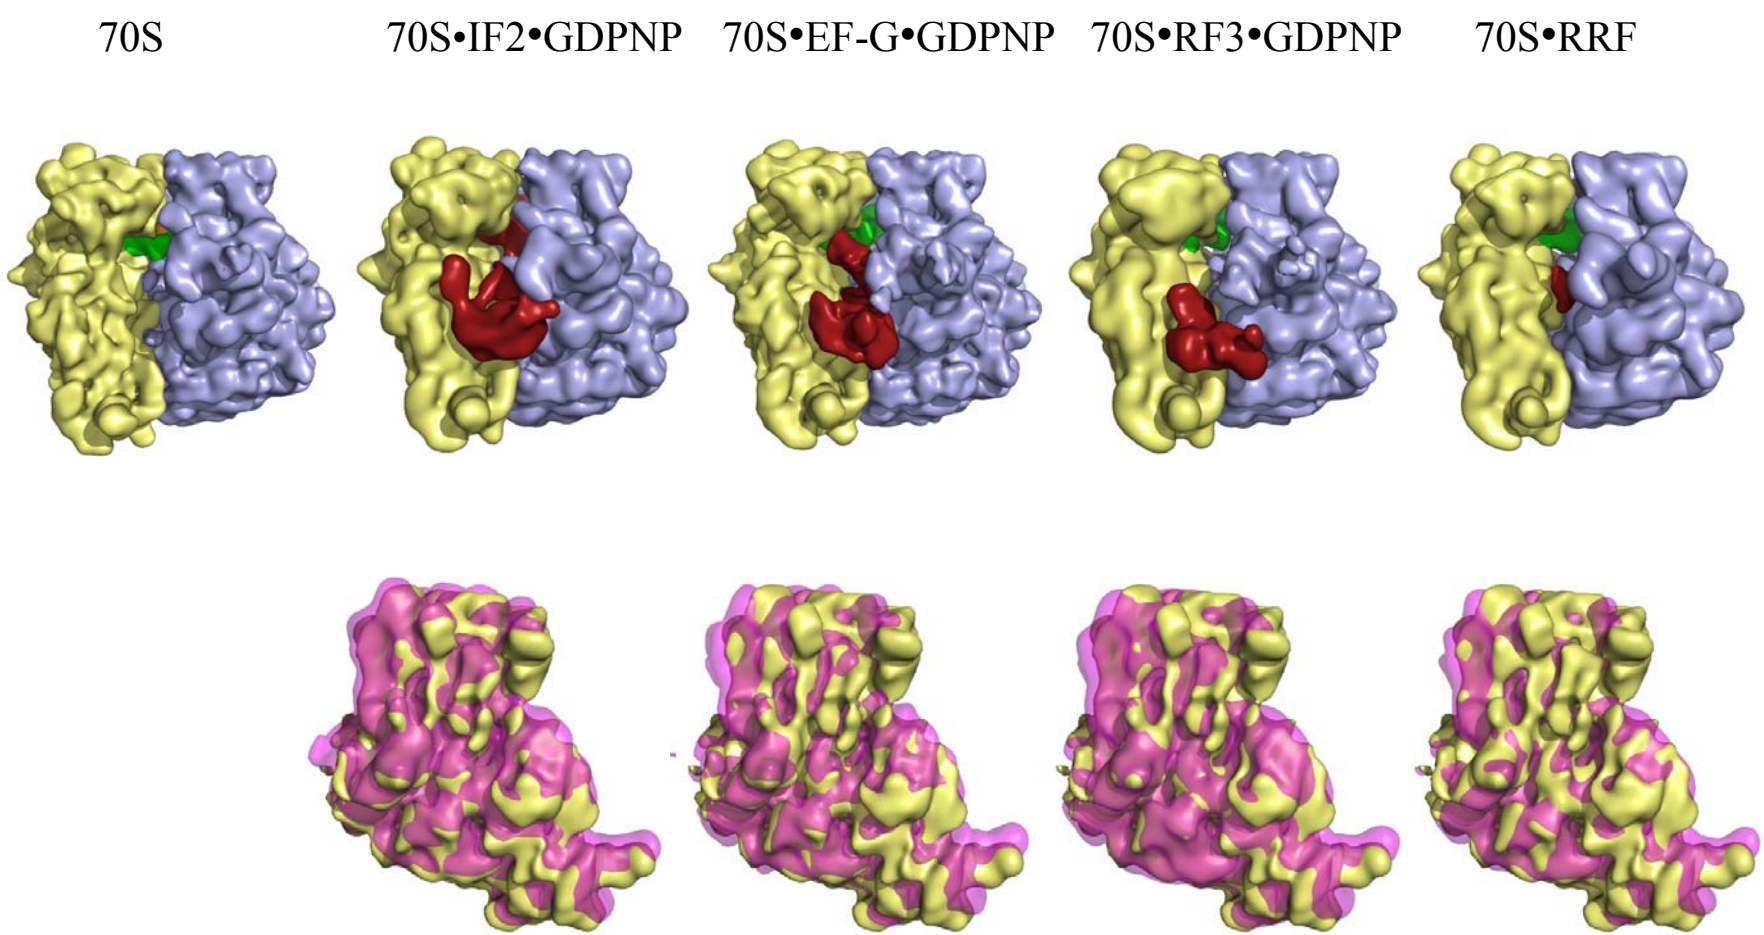
What is the Purpose of the Ratchet Motion in mRNA-tRNA Translocation?

Mechanism of **mRNA translocation** on the small subunit, in two parts

Translocation, Step I:
mRNA moves along with 30S, relative to 50S (lock is closed)

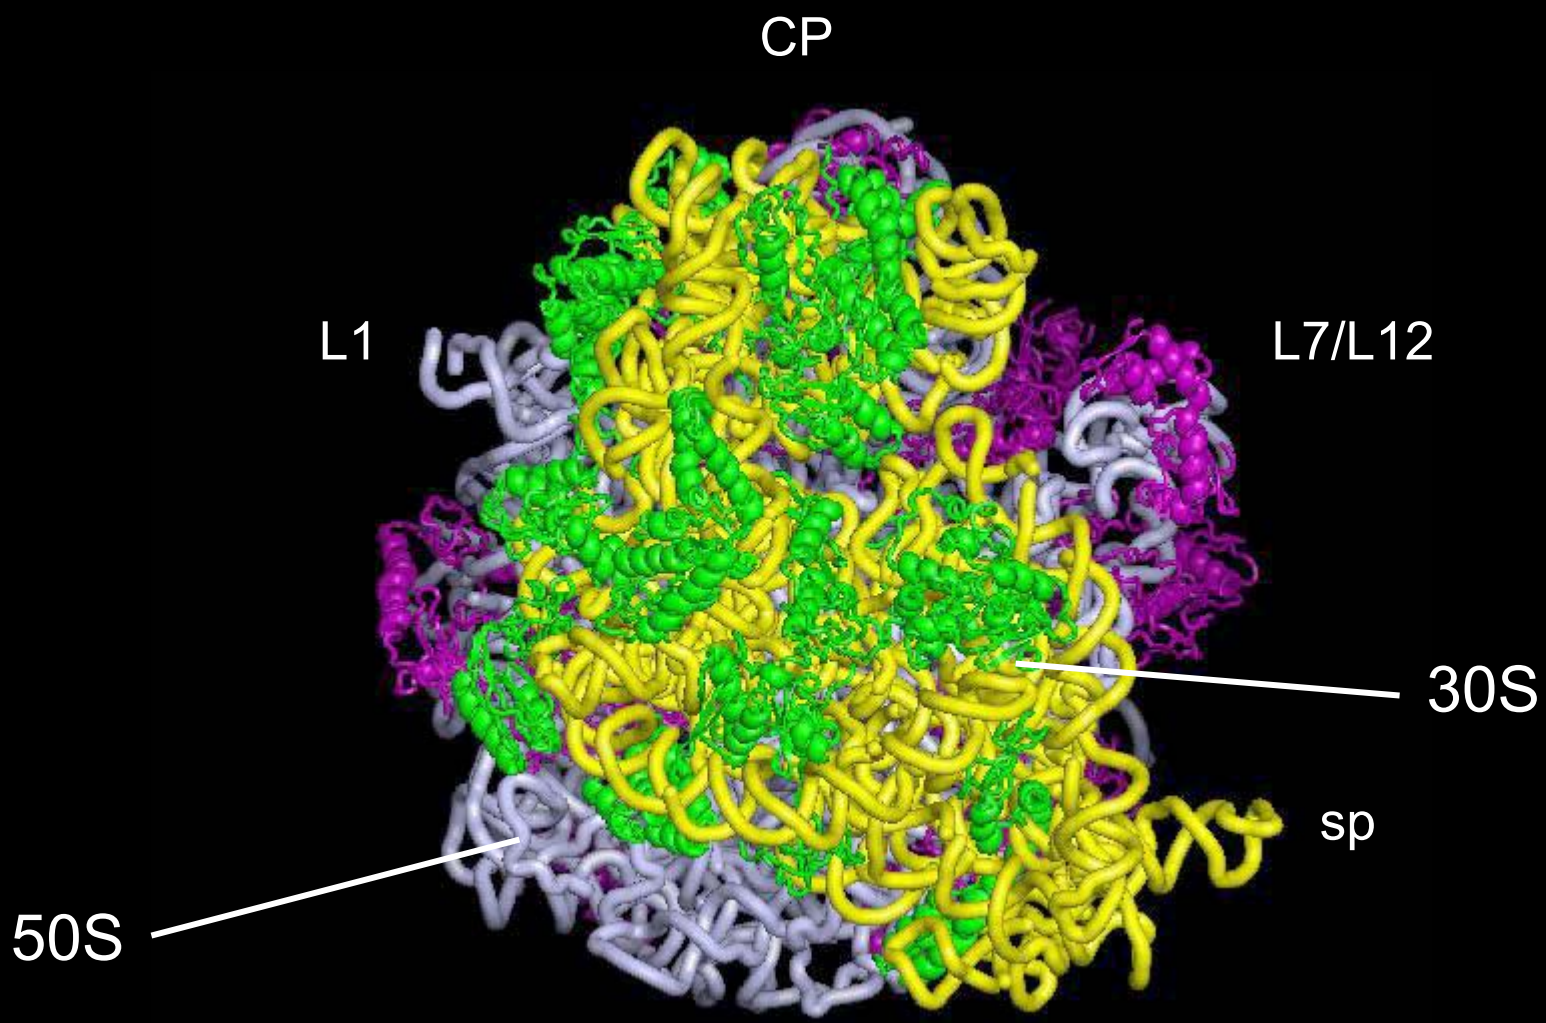
Translocation, Step II:
30S moves back, relative to mRNA and 50S (lock is open)

Modularity of the Machine: Macro-state II is trapped by several factors in entirely different functional contexts. Common mechanism for activating GTPase mechanism?



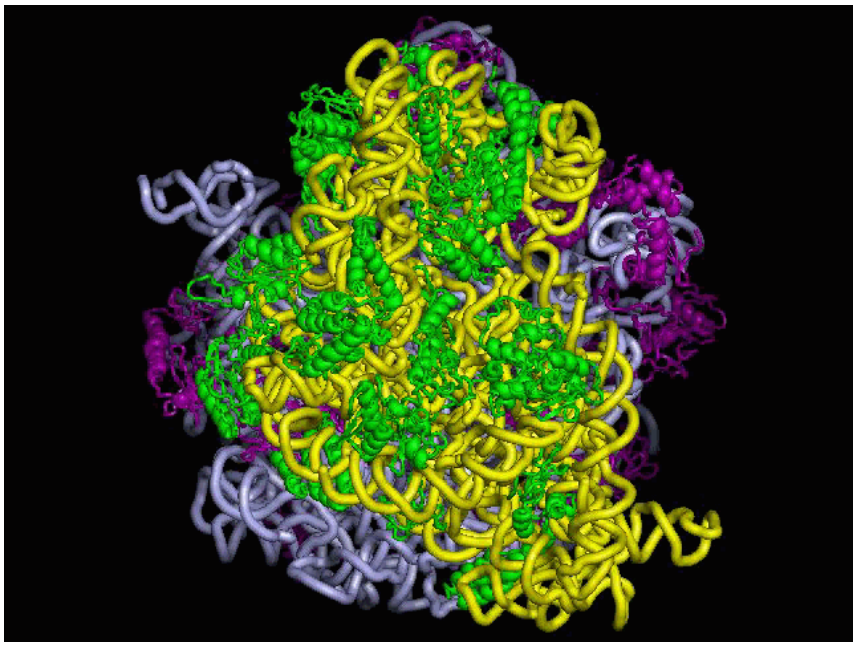
Gabashvili et al., 2000 Allen et al., 2005 Valle et al., 2003 H. Gao et al., subm. N. Gao et al., 2005

Frank & Agrawal, 2000

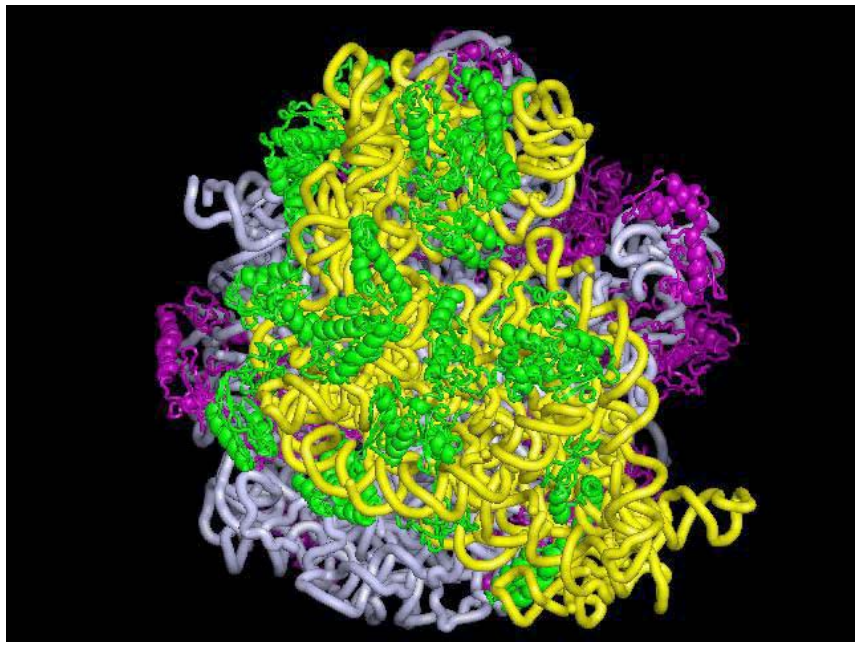


Atomic models of the ratcheting ribosome, upon binding of EF-G (Valle et al. Cell 2003), obtained by real-space refinement (Gao et al., unpublished).

Ratchet motions triggered by EF-G and RF3 are virtually indistinguishable



EF-G



RF3

Evidence for Conformational Changes:

Pb^{2+} induced rRNA cleavage pattern near the peptidyl-transferase center undergoes periodic changes during the elongation cycle

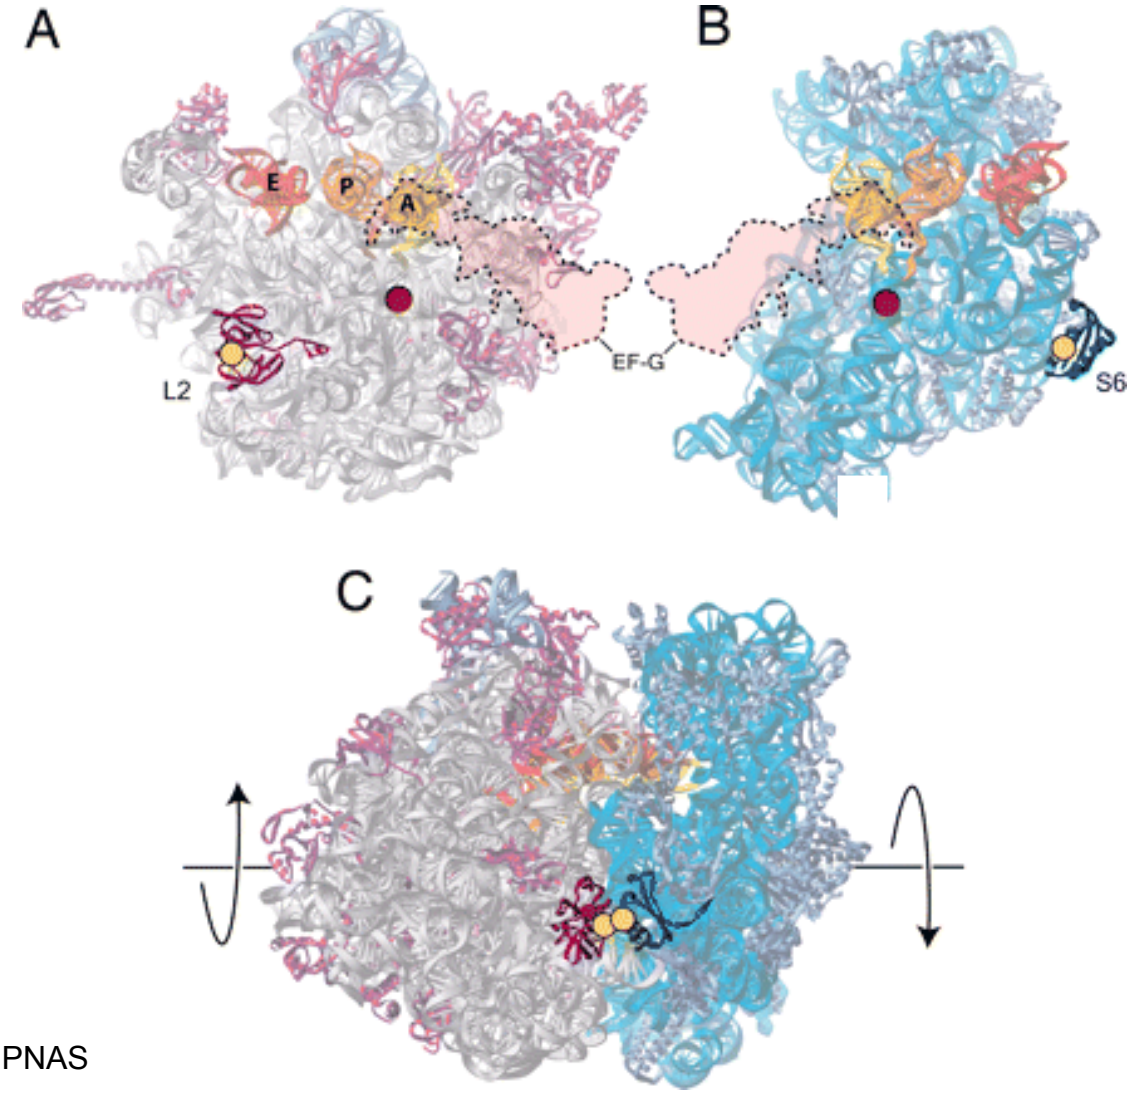
Ratchet motion is necessary for translocation: experimental findings

L2 – S6 cross-link Inhibits translocation



Horan & Noller (2007), PNAS

“Macro-States” of the Ribosome

- The ribosome possesses two “macro-states” (I and II) with distinct conformations that differ by a change in the angle between the subunits (“ratchet motion”)
- *Along with the change in intersubunit angle, a structural reorganization takes place in both subunits, which affects the properties of several sites on both subunits.*
- Although one of the states is preferred, the two macro-states have similar stability, and they appear to be separated by a very small energy barrier (no GTP hydrolysis required to go from one to the other).
- *This transition is instrumental to translocation (recent Noller results), but it will not take place unless the P-site tRNA is deacylated (Zavialov et al., 2003; Valle et al., 2003)*
- Binding of a variety of factors (at the same ribosomal site) temporarily stabilizes state II: EF-G (translocation), IF2 (initiation), RF3 (termination), RRF (recycling).
- *Spontaneous ratcheting (along with transition to P/E state) has been observed by Harry Noller.*

Ratchet motion: example for heterogeneity (one of the many)

- Two populations co-exist:

  (1) non-ratchet + A,P,E (2) ratchet + P/E + EF-G
- Need for classification
- Supervised classification: need to know what we are looking for
- Unsupervised (preferable): no or minimal prior knowledge

  1) “Maximum likelihood” (S. Scheres et al., 2007)

  2) Cluster tracking (Jie Fu & J. Frank, 2006)

  3) Mirek Kalinowski’s/Gabor Herman’s approach of graph cutting (Kalinowski et al., Ultramicroscopy 2007)

Observation of hybrid state (stabilized by EF-G•GDPNP and ratchet motion) by cryo-EM

P/E EF-G

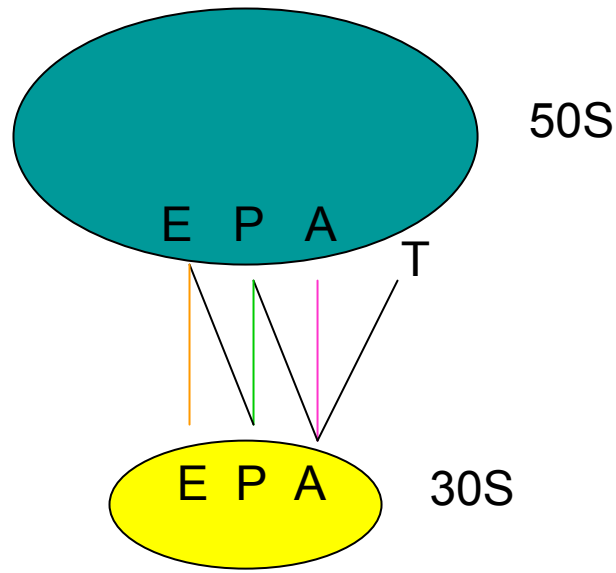
Digression: Passage of tRNA through the ribosome: canonical and hybrid states

tRNA proceeds "one step at the time":

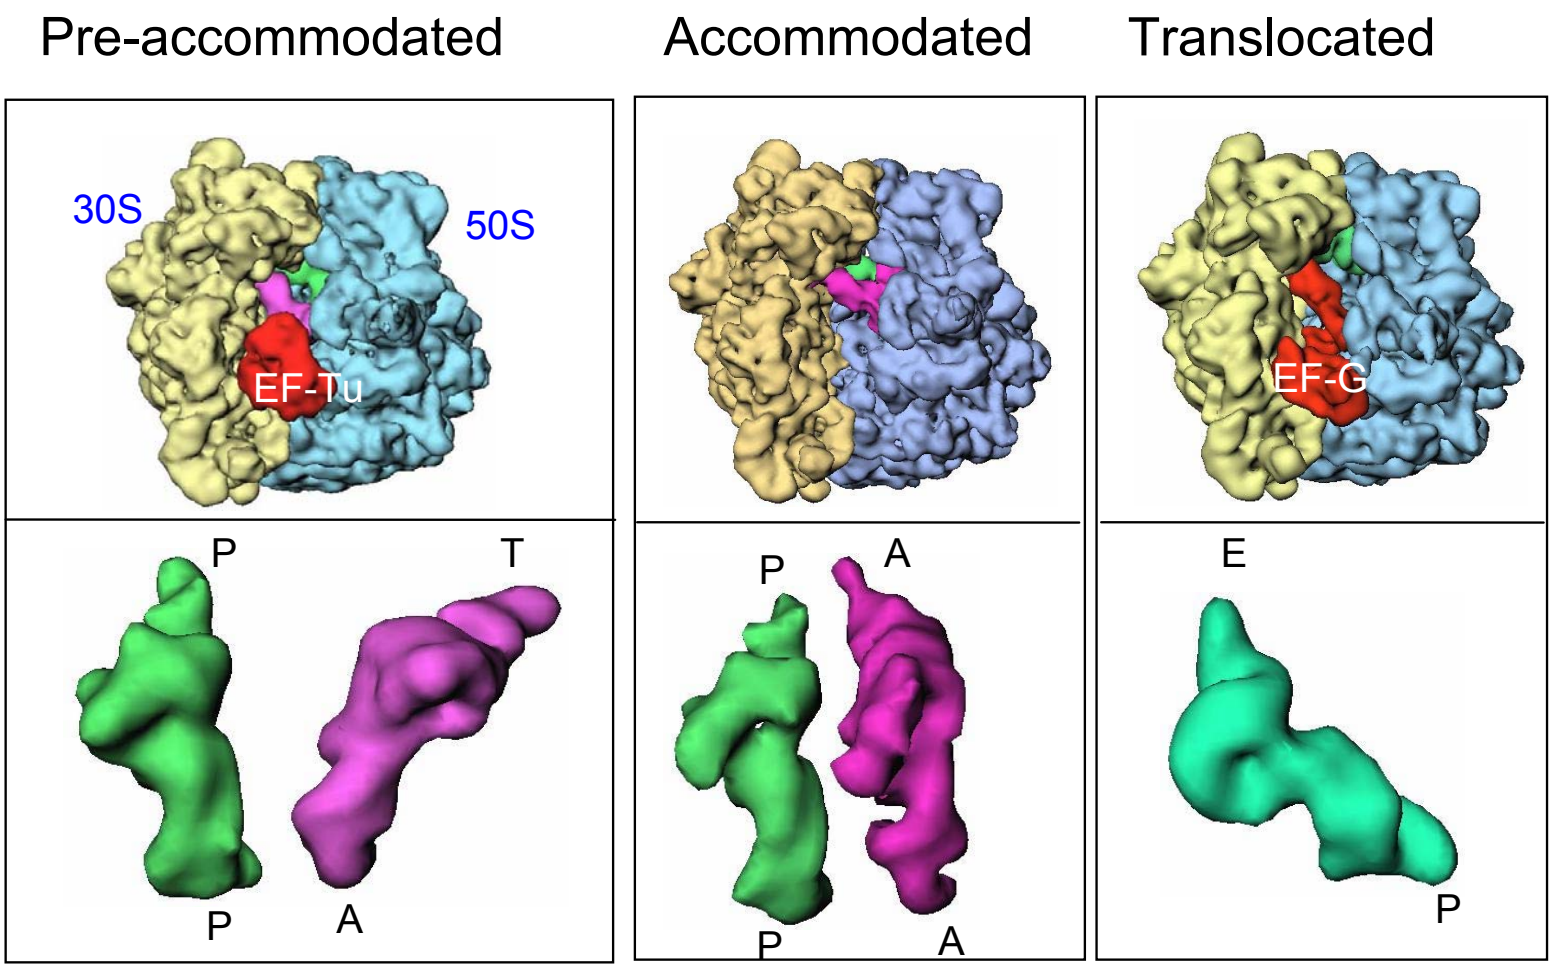
A/T → A/A → A/P → P/P → P/E → E/E

Nomenclature: [position on small subunit] / [position on large subunit]

T bound with EF-Tu
A aminoacyl
P peptidyl
E exit



tRNA observed in cryo-EM maps



Supervised Classification

- Use ribosome maps in both ratchet states but without ligands:
- Successful classification will show tRNAs and EF-G at the expected locations in the two classes.

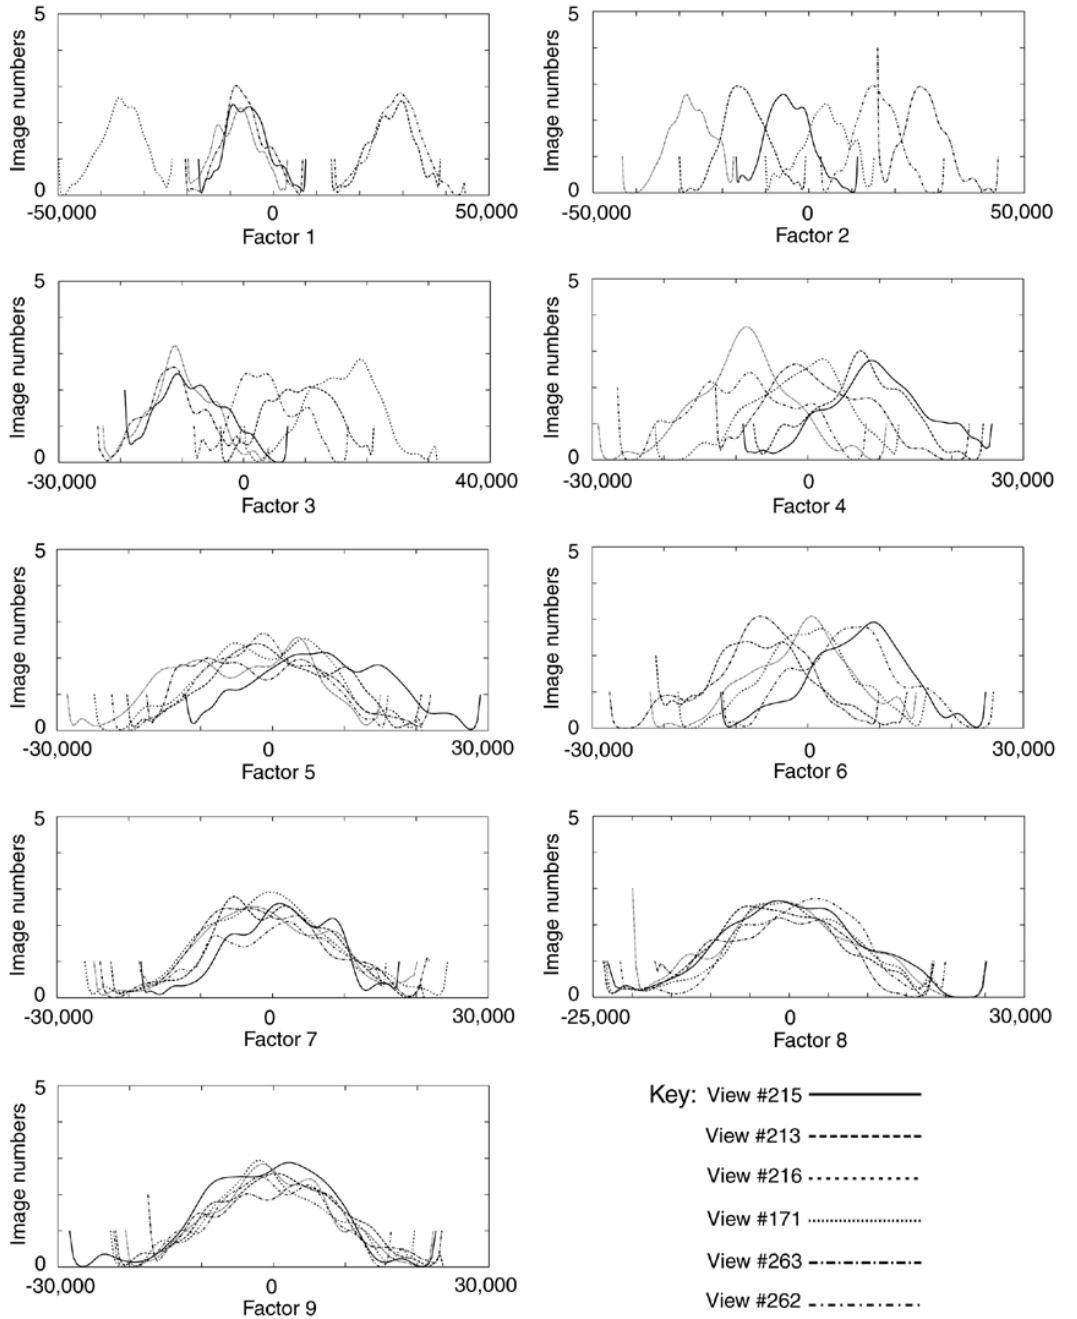
Factors should
not be sensitive to
orientation
(successive exclusion)



#1496 *Journal of Structural Biology* Fu (2007)

Cluster tracking

- Problem of discontinuity of angular distribution
- Solution: (a) collect more data

  (b) use CCCL (cross-correlation of common lines) between clusters established on each “island”.
