

Molecular Tomography - Imaging Molecular Conformation using EM Tilt Series

Outline

1. Why?
2. Methods
 - a. Marker free alignment
 - b. Saxton Rule (cosine rule) angles
 - c. Multivariate Statistical Analysis
 - d. Defocus gradient compensation
3. 3 specimens
 - a. Insect Flight Muscle
 - b. HMM decorated actin
 - c. Actin-villin rafts
 - d. 2-D arrays of myosin V

Why Use Electron Tomography to Determine the Structure of a Macromolecule?

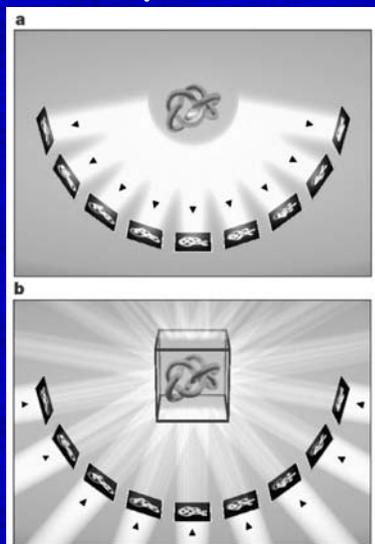

- Your molecule is *big, bad & ugly* & there is not much of it (there may only be one of it)
- You know the structure of your molecule in one context (e.g. in a crystal, detergent) & want to verify its structure in another (e.g. in situ, in a membrane)
- Your molecule is conformationally/ compositionally variable as part of its function (e.g. components bind weakly)
- You need to visualize your molecule in a difficult to trap state, i.e. under tension

4

Tomography Flowchart

Marker Free Alignment

Saxton (cosine) Scheme Tilt Angles

- Specimen thickness (T) increases with tilt angle

$$T_{\alpha} = T_0 / \cos \alpha$$

$\alpha = 60^{\circ}$

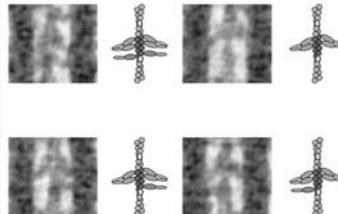

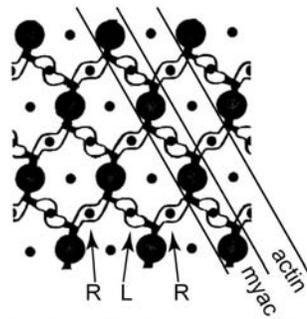

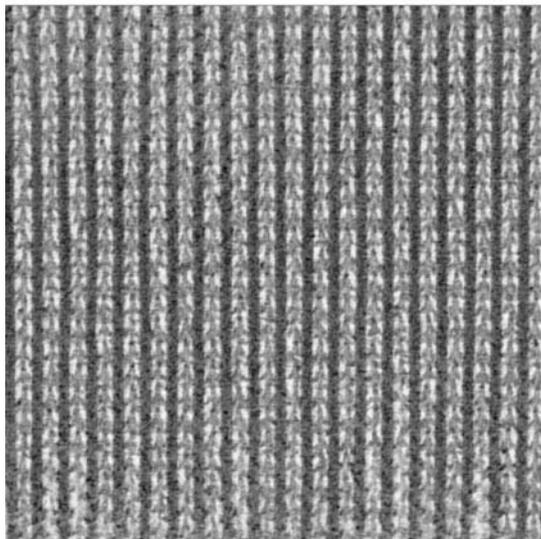

- Tilt increment must decrease to accommodate it

The Missing Wedge - 3 Conditions

1. Repeats (subvolumes) have similar orientation w.r.t missing wedge
2. Repeats differ mainly by rotation about z
3. Repeats differ in rotation about all 3 Euler angles

NRAMM – Tomography Workshop

14

20 Class Averages from IFM Rigor

- Dual axis tomogram (on film)
- Hierarchical Ascendant Classification (HAC)
- Multireference alignment
- Not all classes average the same number of repeats
- Resolution ~7 nm

11/12/2007

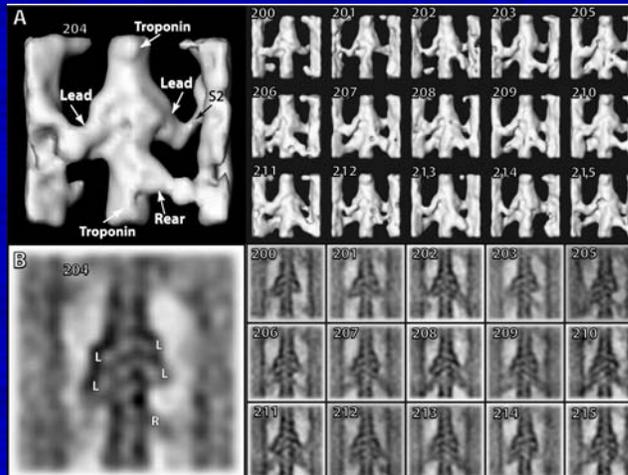

NRAMM – Tomography Workshop

16

Stretch Rigor Fiber - Class Averages

- Single reference alignment - each repeat aligned on a thin filament reference
- Classify with a mask that includes crossbridges, & no thin filament

11/12/2007

NRAMM - Tomography Workshop

17

Alignment & Classification Scheme

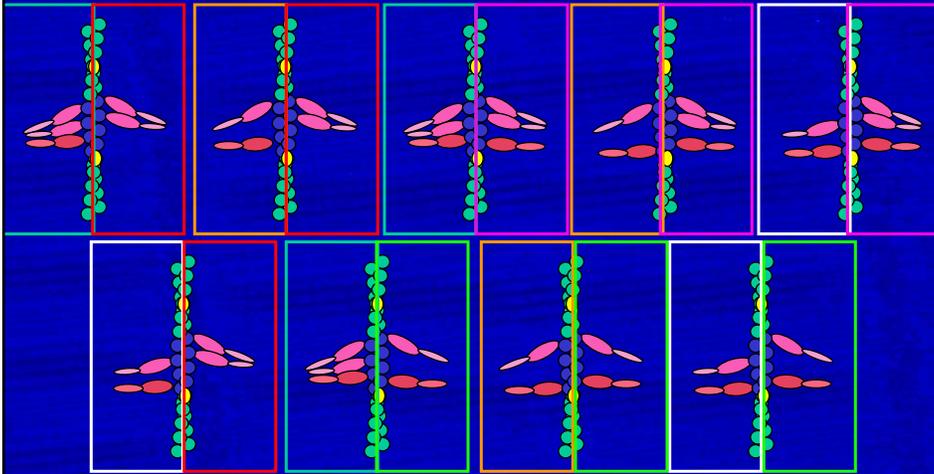

- I. Align each of N repeats (38.5 nm actin periods) on the actin filament
- II. Classify the repeats based on the crossbridges
 - A. How many classes?
- III. 2 classification models
 - A. Create $N^{1/2}$ class averages of complete repeats
 - B. Classify separately left & right sides of actin filaments
 1. $N^{1/2}$ left side class averages
 2. $N^{1/2}$ right side class averages
 - C. Signal to noise improvement is $N^{1/4}$ for both models
- IV. Then reassemble the tomogram by replacing the raw repeats with the class averages
 - A. $N^{1/2}$ class averages of complete repeats
 - B. $N^{1/2} * N^{1/2} = N$ class averages reconstituted from left & right sides

Taming "The Big, the Bad & the Ugly"

1. Efficient subvolume alignment & averaging techniques absolutely essential
2. Multivariate Statistical Analysis (classification) is an important component for extracting molecular conformations from subvolumes
3. ~20Å possible from tomograms of ice embedded specimens

11/12/2007 NRAMM – Tomography Workshop 26

Visualizing Active Muscle Crossbridges

Multivariate Data Analysis of Subvolumes from Tomograms of Quick-frozen, Ca²⁺-activated Isometrically Contracting Insect Flight Muscle Reveals Unconventional Cross-bridge Conformations

2

Insect flight muscle (IFM)

HST state--the experimental model

- The fully active isometric state in IFM
- High static tension (HST) state: it can reach tension levels comparable to stretch activation.
- Active cross-bridges show a wide range of attachment angles, from pre-stroke to rigor-like end-stroke.

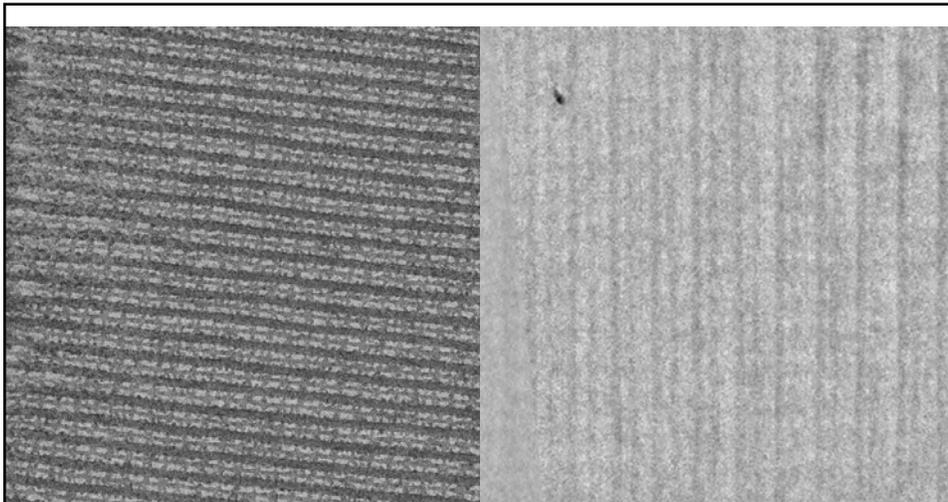

4

Bridges outside of actin target-zone

- Unique properties of IFM thin filament and myosin head:
 - High molecular weight tropomyosin isoforms (historically called “heavy troponin”, TnH)
 - Tn isoforms with different Calcium affinity (F1, F2)
 - Myosin regulatory light chain N-terminal extension

Links between thick and thin filaments other than the predominant target zone bridges.

5

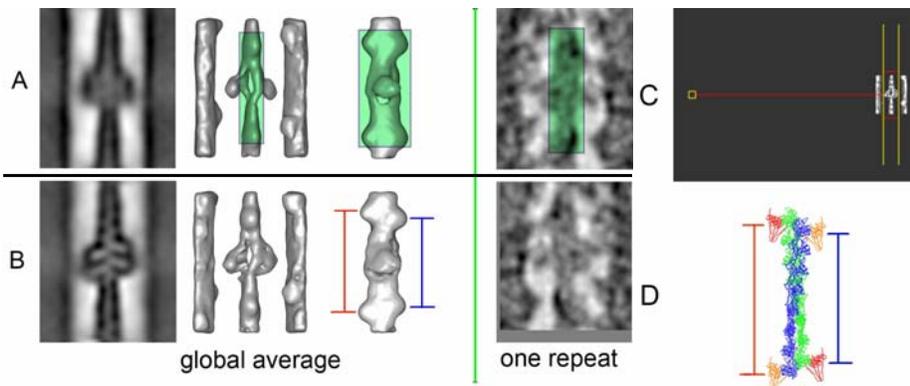

- (a) collect 2D images that are projections of a 3D object at various orientations
- (b) a 3D image of the object is reconstructed by projecting all 2D images back into a common volume

3D image (repeat sub-volume) processing

- 1. Sub-volume extraction
- 2. Sub-volume alignment
- 3. Masks for multivariate data analysis (MDA)
- 4. MDA and classification
- 5. Repeat reassembly

7

Repeat Sub-volume Alignment

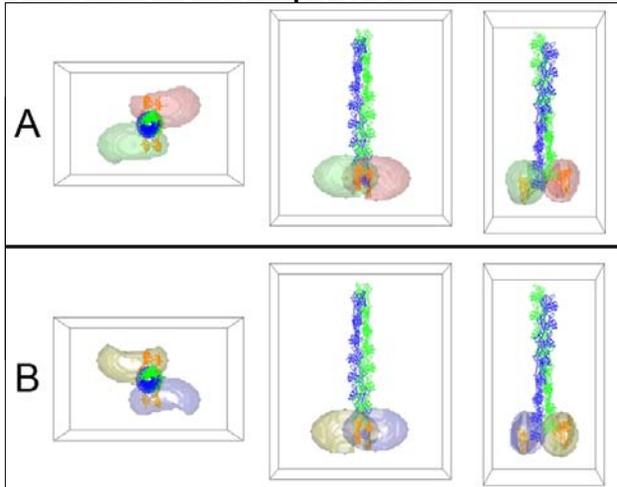

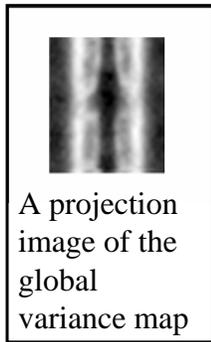

- **A:** before alignment; **B:** after alignment.
- Alignment involves x, y, & z translation and 180° rotation along the thin filament axis.

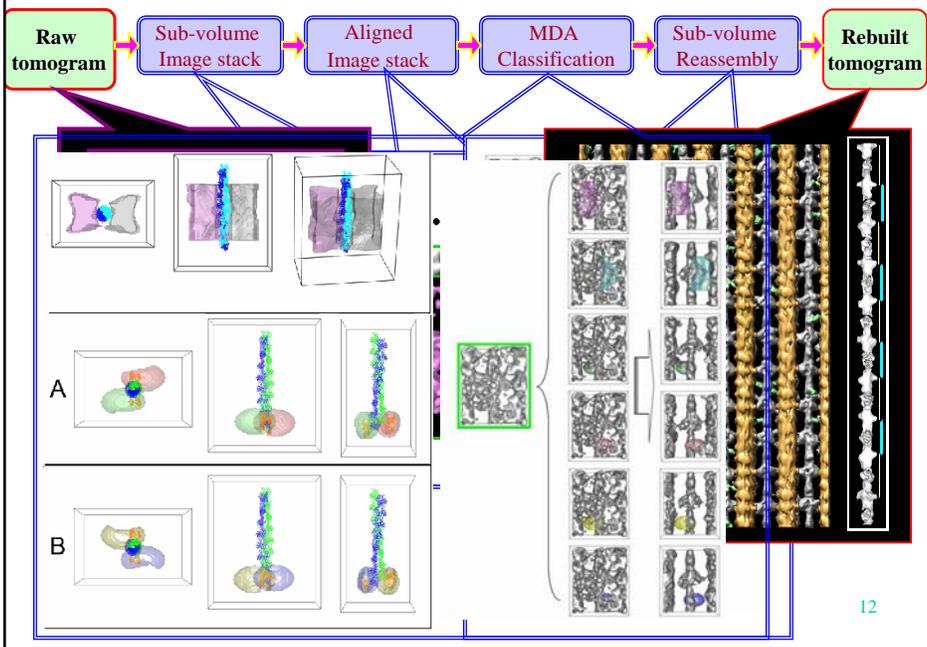

8

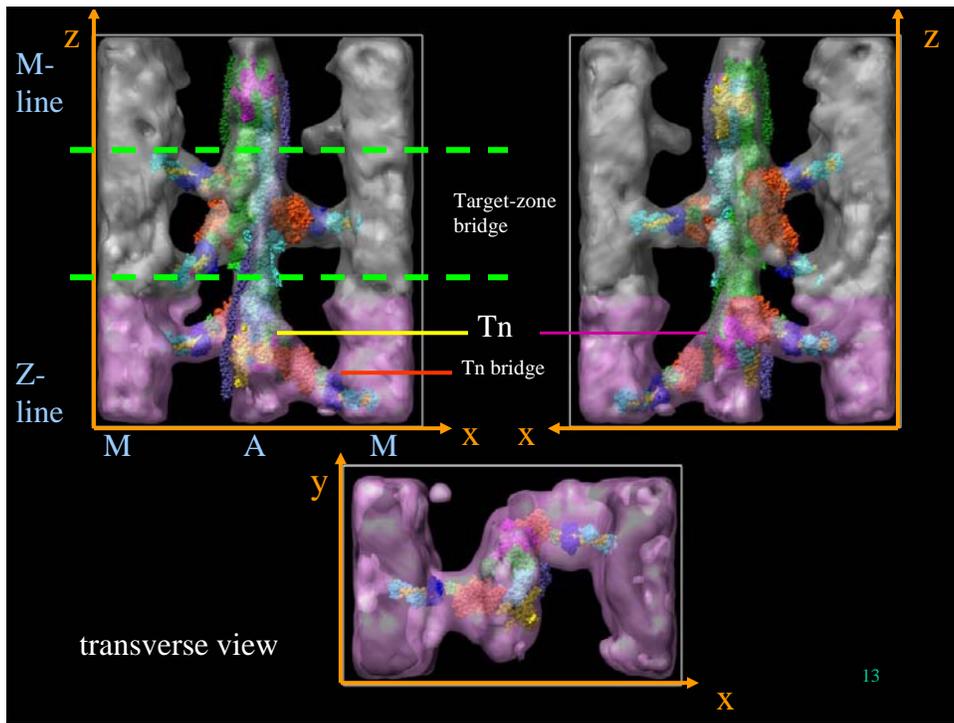

Masks for MDA

- Only those pixels within the mask are subjected to MDA. Pixels outside the mask are excluded from the computation.

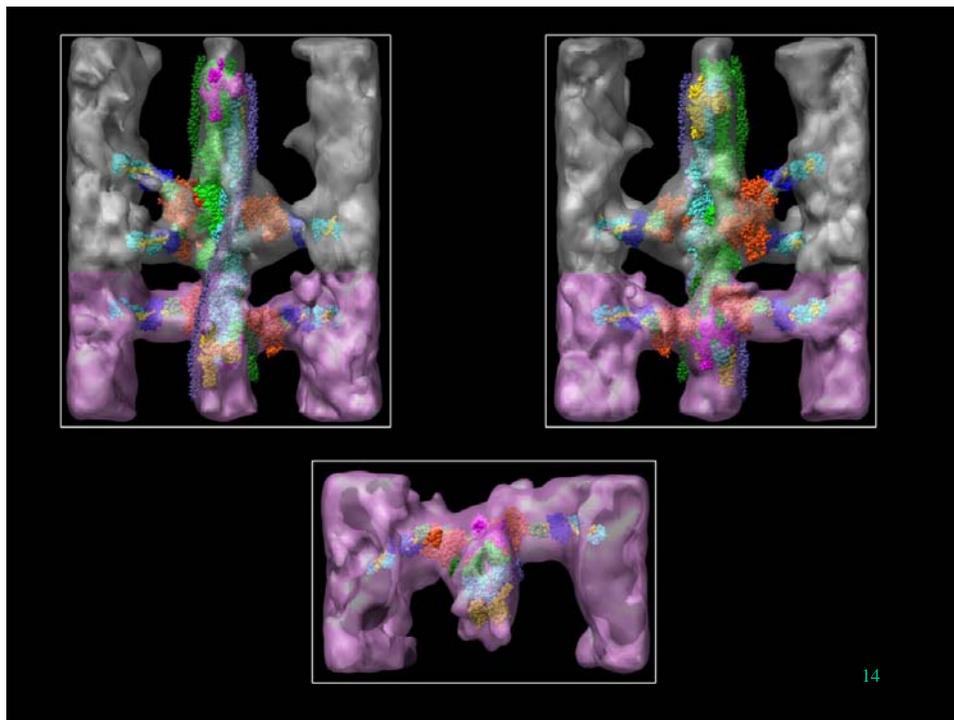

Journey of a cross-bridge repeat sub-volume

13

14

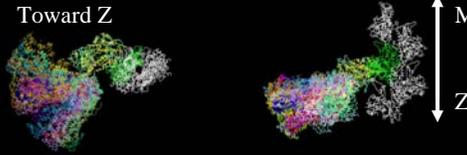

Evaluation and analysis

- Model fitting (fit atomic structures into class averages)

Motor domain in strong binding configuration.

Starting model--
Upper: Rigor ([Holmes KC 2003](#))
Bottom: transition scallop ([Houdusse A 2000](#))

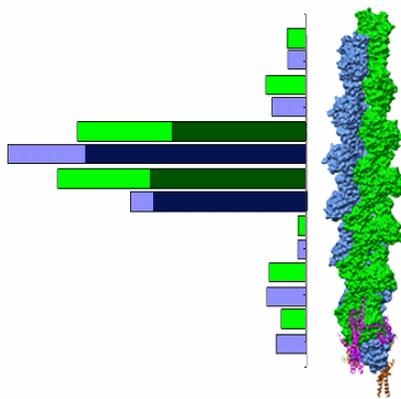

Toward Z

Motor domain deviated from the strong binding position

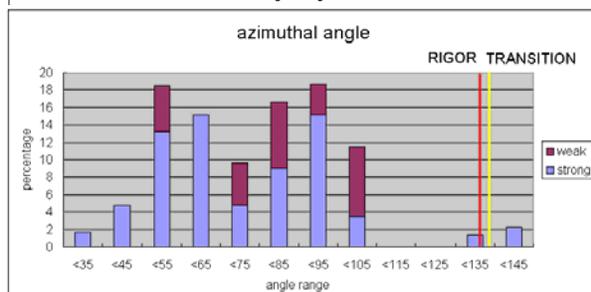

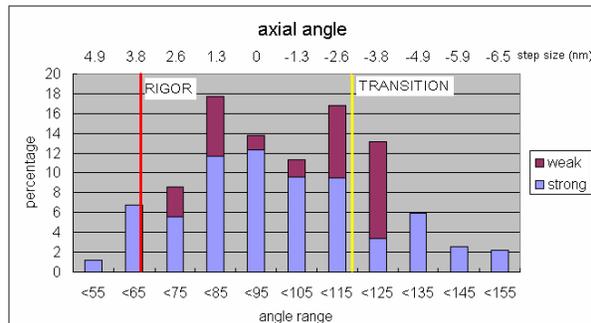

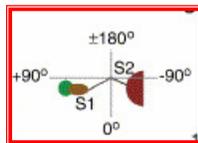

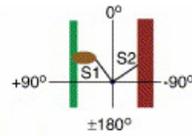

Actin occupancy by myosin heads

- Target-zone: actin H, I, J, K
- ~71% of target-zone bridges are at strong binding configuration

16

2 - lever arm

SUMMARY

- The revised image processing technique reveals many unconventional cross-bridge conformations
 - a broad distribution of lever arm angles of strong binding bridges
 - weak binding bridges on target-zone
 - bridges formed outside of target-zone, e.g. Tn region
- Model fitting provides information beyond the resolution of density maps and helps the characterization of different bridges
- MDA and classification as data reduction tools, facilitate the statistics (e.g. actin occupancy, angle distribution)

- **insect flight muscle is not a Struct. Biol.** 138, 92-104
- Liu et al., (2004) Electron tomography of fast frozen, stretched rigor fibers reveals elastic distortions in the myosin crossbridges. *J. Struct. Biol.* 147, 268–282.
- Limited resolution

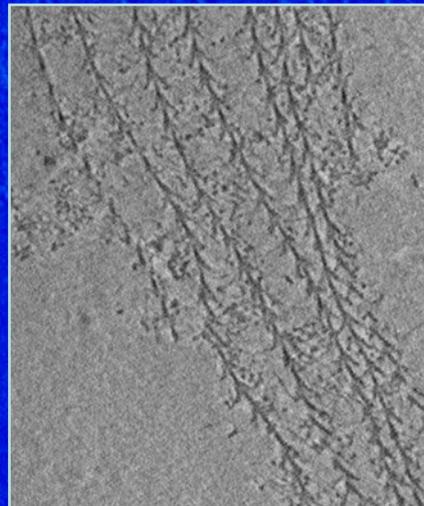

Conditions

- Cryoelectron tomography to obtain 3-D image
- Acto-HMM rafts formed on a lipid monolayer by polymerizing actin in the presence of HMM
- Conditions –
 - 1 mM ADP, 20 mM Pi, 2 mM Mg²⁺, 80 mM KCl
- A novel approach developed to obtain the 3-D averaged structure of acto-HMM

Structure of the Villin-Actin Cross-link using Single-Particle Analysis of 3D Volumes

Cheri Hampton
Taylor Lab
Institute of Molecular Biophysics
Florida State University

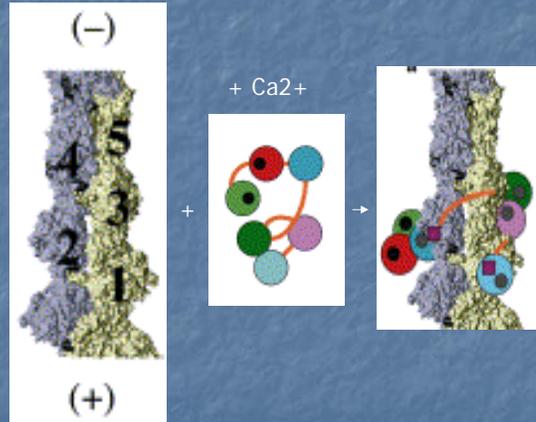

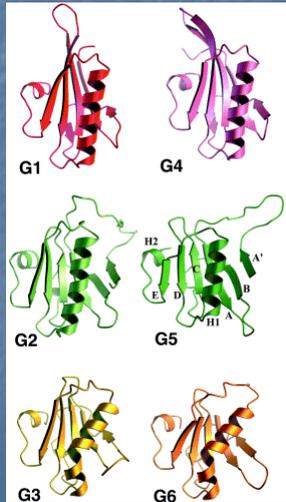

Introduction to Villin

- An 95 kD actin nucleating, cross-linking, severing and capping protein found in microvilli along with fimbrin
- Cross-links w/o calcium, requires high calcium or phosphorylation to activate severing and capping
- 45% sequence identity to gelsolin
- Has a C-term "head-piece" domain that confers cross-linking ability
- There is one crystal structure for the 1st gelsolin-like domain and an NMR structure for "head-piece" and HP + 6th gelsolin-like domain
- Assumed to bind/ sever F-actin similar to gelsolin

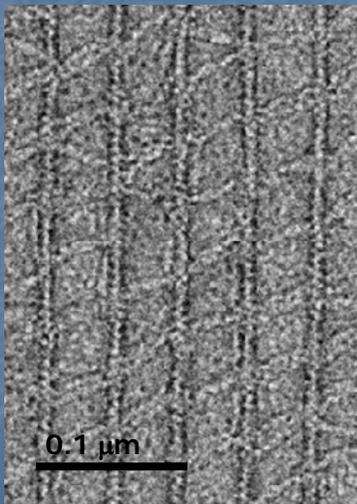

Gelsolin Structure and Function

Gelsolin severing and capping model adapted from McGough, et. al. 2003. *FEBS Letters*, 552(2-3):75-81.

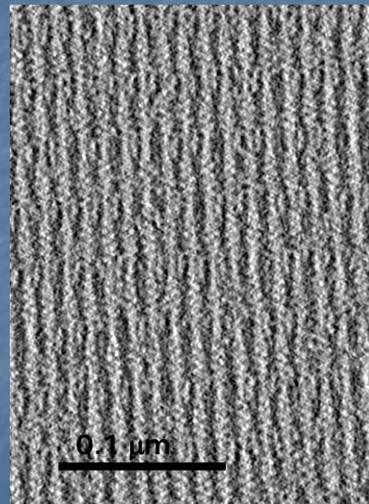

Villin Forms a Tight Bundle

α -Actinin-F-actin Rafts

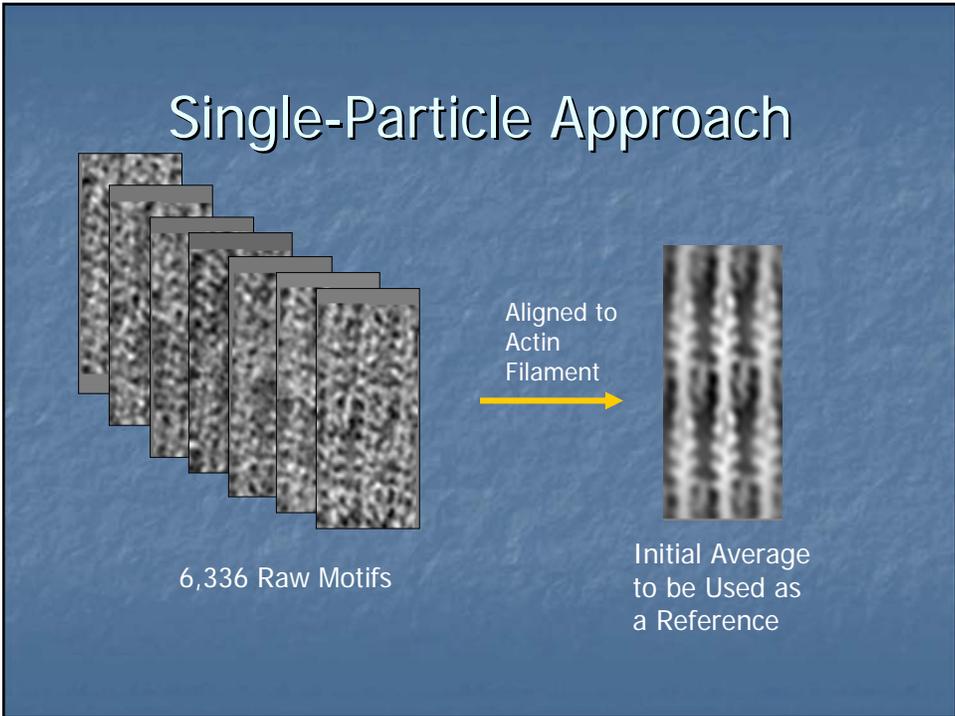

Inter-Filament distance= ~390 A

Villin-F-actin Rafts

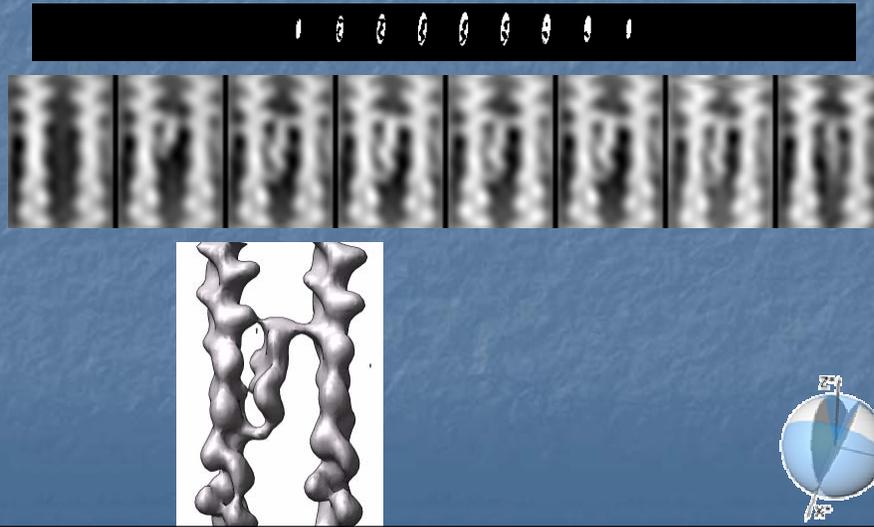

Inter-Filament distance= ~126 A

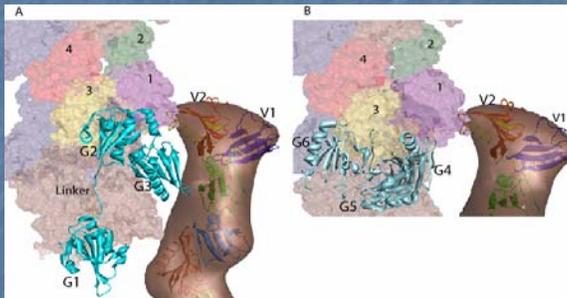

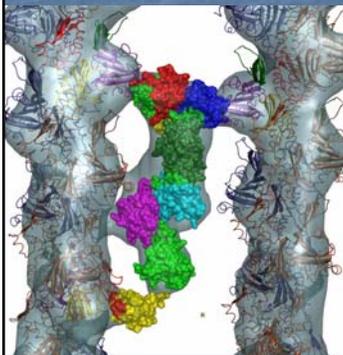

Villin Cross-Links are Homogeneous

6,356 total repeats were sorted into classes based on variance

Non-quantitative
positioning of gelsolin
domains plus HP

Villin and gelsolin binding
sites do not overlap.

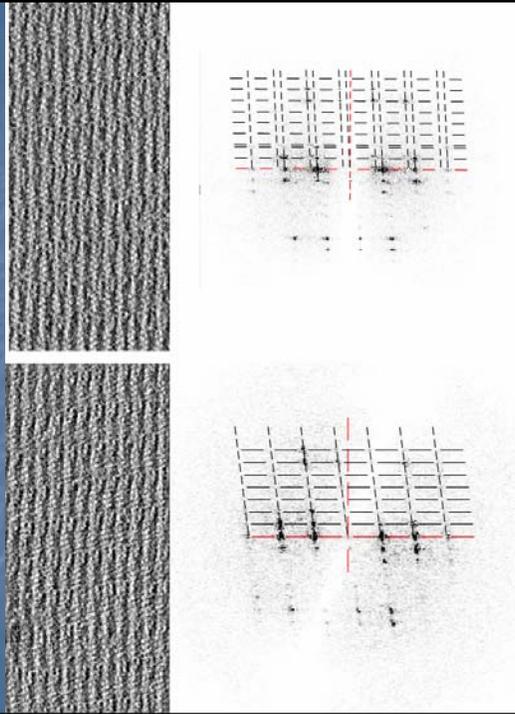

Gelsolin N-terminus
(PDB 1RG1) docked
onto F-actin. Note that
G1 is capping the
filament end.

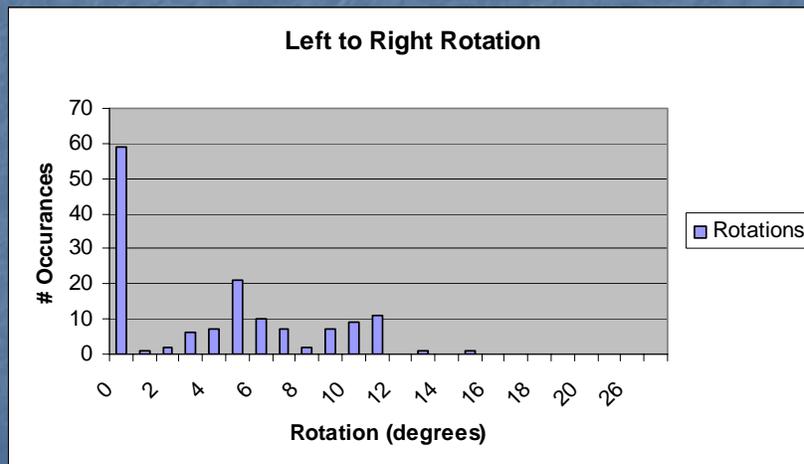

Gelsolin C-
terminus (PDB
1H1V) docked
onto F-actin.

Raft Analysis

- Actin symmetry varies: 13/6, 80/37, 186/86
- Interfilament spacing ~126Å
- Axial shift of 17Å from left to right filament
- Axial rotation of the right filament relative to left is 0, 5, 10 degrees
- Diffraction spots out to 28Å resolution

Filament Rotations from Class Averages

JSB. 2003, 43:24*

3-D Average of Flower Motif

Challenges

1. How many different structures you looking for?
2. Resolution & Signal/Noise Improvement
 - a. Keep in mind that resolution ultimately depends on the tilt angle increment
 - b. Once S/N improvement reaches the resolution limit, there is no further improvement
3. What is the resolution limit for biological tomography?
 - a. Subvolume averaging
 - b. CTF correction
